

Cypher is the declarative query language for Neo4j, the world's leading graph database.

Key principles and capabilities of Cypher are as follows:

- Cypher matches patterns of nodes and relationship in the graph, to extract information or modify the data.
- Cypher has the concept of identifiers which denote named, bound elements and parameters.
- Cypher can create, update, and remove nodes, relationships, labels, and properties.
- Cypher manages indexes and constraints.

You can try Cypher snippets live in the Neo4j Console at console.neo4j.org or read the full Cypher documentation in the Neo4j Developer Manual. For live graph models using Cypher check out **GraphGist**.

The Cypher Refcard is also <u>available in PDF format</u>.

Note: {value} denotes either literals, for ad hoc Cypher queries; or parameters, which is the best practice for applications. Neo4j properties can be strings, numbers, booleans or arrays thereof. Cypher also supports maps and lists.

Syntax

Read Query Structure

[MATCH WHERE] [OPTIONAL MATCH WHERE]

[WITH [ORDER BY] [SKIP] [LIMIT]]

RETURN [ORDER BY] [SKIP] [LIMIT]

MATCH

MATCH (n:Person)-[:KNOWS]->(m:Person)

WHERE n.name = 'Alice'

Node patterns can contain labels and properties.

MATCH (n)-->(m)

Any pattern can be used in MATCH.

MATCH (n {name: 'Alice'})-->(m)

Patterns with node properties.

MATCH p = (n) --> (m)

Assign a path to p.

OPTIONAL MATCH (n)-[r]->(m)

Optional pattern, `null`s will be used for missing parts.

WHERE m.name = 'Alice'

Force the planner to use a label scan to solve the query (for manual performance tuning).

WHERE

WHERE n.property <> \$value

Use a predicate to filter. Note that where is always part of a MATCH, OPTIONAL MATCH, WITH or START clause. Putting it after a different clause in a query will alter what it does.

Write-Only Query Structure

(CREATE [UNIQUE] | MERGE)* [SET|DELETE|REMOVE|FOREACH]*

[RETURN [ORDER BY] [SKIP] [LIMIT]]

Read-Write Query Structure

[MATCH WHERE] [OPTIONAL MATCH WHERE]

[WITH [ORDER BY] [SKIP] [LIMIT]]

(CREATE [UNIQUE] | MERGE)* [SET|DELETE|REMOVE|FOREACH]*

[RETURN [ORDER BY] [SKIP] [LIMIT]]

CREATE

CREATE (n {name: \$value})

Create a node with the given properties.

CREATE (n \$map)

Create a node with the given properties. UNWIND \$listOfMaps AS properties

CREATE (n) SET n = properties

Create nodes with the given properties.

CREATE (n)-[r:KNOWS]->(m)

Create a relationship with the given type and direction; bind a variable to it.

CREATE (n)-[:LOVES {since: \$value}]->(m) Create a relationship with the given type, direction, and

SET

SET n.property1 = \$value1, n.property2 = \$value2

Update or create a property.

SET n = \$map

properties.

Set all properties. This will remove any existing properties.

SET n += \$map

Add and update properties, while keeping existing ones.

SET n:Person

Adds a label Person to a node.

REMOVE

REMOVE n:Person Remove a label from n.

REMOVE n.property

Remove a property.

RETURN

RETURN *

Return the value of all variables.

RETURN n AS columnName

Use alias for result column name.

RETURN DISTINCT n

Return unique rows.

ORDER BY n.property

Sort the result.

ORDER BY n.property DESC Sort the result in descending order.

SKIP \$skipNumber

Skip a number of results.

LIMIT \$limitNumber Limit the number of results.

SKIP \$skipNumber LIMIT \$limitNumber

Skip results at the top and limit the number of results.

RETURN count(*)

The number of matching rows. See Aggregation for more.

WITH

MATCH (user)-[:FRIEND]-(friend)

WHERE user.name = \$name

WITH user, count(friend) AS friends WHERE friends > 10

RETURN user

The WITH syntax is similar to RETURN. It separates query parts explicitly, allowing you to declare which variables to carry over to the next part.

MATCH (user)-[:FRIEND]-(friend)

WITH user, count(friend) AS friends ORDER BY friends DESC

SKIP 1

LIMIT 3 RETURN user

You can also use ORDER BY, SKIP, LIMIT with WITH.

UNION

MATCH (a)-[:KNOWS]->(b) RETURN b.name

UNION

MATCH (a)-[:LOVES]->(b)

RETURN b.name

Returns the distinct union of all query results. Result column types and names have to match.

MATCH (a)-[:KNOWS]->(b)

RETURN b.name

UNION ALL MATCH (a)-[:LOVES]->(b)

RETURN b.name

Returns the union of all query results, including duplicated rows.

MERGE

MERGE (n:Person {name: \$value}) ON CREATE SET n.created = timestamp()

ON MATCH SET n.counter = coalesce(n.counter, 0) + 1,

n.accessTime = timestamp() Match pattern or create it if it does not exist. Use on

CREATE and ON MATCH for conditional updates.

MATCH (a:Person {name: \$value1}), (b:Person {name: \$value2})

MERGE (a)-[r:LOVES]->(b)

MERGE finds or creates a relationship between the nodes.

MATCH (a:Person {name: \$value1})

MERGE

(a)-[r:KNOWS]->(b:Person {name: \$value3}) MERGE finds or creates subgraphs attached to the node.

DELETE

DELETE n, r

Delete a node and a relationship.

DETACH DELETE n

Delete a node and all relationships connected to it.

DETACH DELETE n

MATCH (n)

Delete all nodes and relationships from the database.

FOREACH

FOREACH (r IN rels(path) | SET r.marked = true)

Execute a mutating operation for each relationship of a path.

FOREACH (value IN coll | CREATE (:Person {name: value}))

Execute a mutating operation for each element in a list.

CALL

CALL db.labels() YIELD label

This shows a standalone call to the built-in procedure db.labels to list all labels used in the database. Note that required procedure arguments are given explicitly in brackets after the procedure name.

CALL java.stored.procedureWithArgs

Standalone calls may omit YIELD and also provide arguments implicitly via statement parameters, e.g. a standalone call requiring one argument input may be run by passing the parameter map {input: 'foo'}.

CALL db.labels() YIELD label RETURN count(label) AS count

Calls the built-in procedure db.labels inside a larger

query to count all labels used in the database. Calls inside a larger query always requires passing arguments and naming results explicitly with YIELD.

START

START n = node:nodeIndexName(key = \$value) Query the index named nodeIndexName with an exact

query. Use node_auto_index for the automatic index. Note that other uses of START have been removed as of Cypher 2.2.

```
INDEX
```

CREATE INDEX ON :Person(name)

Create an index on the label Person and property name.

MATCH (n:Person) WHERE n.name = \$value

An index can be automatically used for the equality comparison. Note that for example lower(n.name) = \$value will not use an index.

MATCH (n:Person)

WHERE n.name IN [\$value]

An index can be automatically used for the IN list checks.

MATCH (n:Person)

USING INDEX n:Person(name) WHERE n.name = \$value

Index usage can be enforced, when Cypher uses a suboptimal index or more than one index should be used.

DROP INDEX ON :Person(name)

Drop the index on the label Person and property name.

CONSTRAINT

CREATE CONSTRAINT ON (p:Person) ASSERT p.name IS UNIQUE

Create a unique property constraint on the label Person and property name. If any other node with that label is updated or created with a name that already exists, the write operation will fail. This constraint will create an accompanying index.

DROP CONSTRAINT ON (p:Person) ASSERT p.name IS UNIQUE

Drop the unique constraint and index on the label Person and property name.

CREATE CONSTRAINT ON (p:Person)

ASSERT exists(p.name) Create a node property existence constraint on the label Person and property name. If a node with that label is created without a name, or if the name property is removed from an existing node with the Person label, the write

DROP CONSTRAINT ON (p:Person) ASSERT exists(p.name)

operation will fail.

Drop the node property existence constraint on the label Person and property name.

CREATE CONSTRAINT ON ()-[1:LIKED]-() ASSERT exists(l.when)

Create a relationship property existence constraint on the type LIKED and property when. If a relationship with that type is created without a when, or if the when property is removed from an existing relationship with the LIKED type, the write operation will fail.

ASSERT exists(l.when) Drop the relationship property existence constraint on

LOAD CSV FROM 'http://neo4j.com/docs/3.1.1/cypher-

DROP CONSTRAINT ON ()-[1:LIKED]-()

the type LIKED and property when.

refcard/csv/artists.csv' AS line CREATE (:Artist {name: line[1], year: toInt(line[2])}) Load data from a CSV file and create nodes.

Comparison	=, <>, <, >, <=, >=
Boolean	AND, OR, XOR, NOT
String	+
List	+, IN, [x], [x y]
Regular Expression	=~
String matching	STARTS WITH, ENDS WITH, CONTAINS

null

• null is used to represent missing/undefined values.

• null is not equal to null. Not knowing two values does not imply that they are the same value. So the expression null = null yields null and not true. To check if an expression is null, use IS NULL.

• Arithmetic expressions, comparisons and function calls

(except coalesce) will return null if any argument is null. • An attempt to access a missing element in a list or a

property that doesn't exist yields null. • In OPTIONAL MATCH clauses, nulls will be used for missing parts of the pattern.

CREATE UNIQUE

CREATE UNIQUE (n)-[:KNOWS]->(m {property: \$value})

Match pattern or create it if it does not exist. The pattern

can not include any optional parts.

(m)<-[:KNOWS]-(n) element of the list. Relationship of type KNOWS from n to m. none(x IN coll WHERE exists(x.property)) (n)-[:KNOWS|:LOVES]->(m) Returns true if the predicate is false for all elements of Relationship of type KNOWS or of type LOVES from n to m. the list. $(n)-[\Gamma]->(m)$ single(x IN coll WHERE exists(x.property)) Bind the relationship to variable r. Returns true if the predicate is true for exactly one (n)-[*1..5]->(m)element in the list. Variable length path of between 1 and 5 relationships size(\$list) AS len, \$list[0] AS value from n to m. <u>Functions</u> (n)-[*]->(m)coalesce(n.property, \$defaultValue) Variable length path of any number of relationships from The first non-null expression. n to m. (Please see the performance tips.) timestamp() (n)-[:KNOWS]->(m {property: \$value}) Milliseconds since midnight, January 1, 1970 UTC. A relationship of type knows from a node n to a node m id(nodeOrRelationship) with the declared property. The internal id of the relationship or node. shortestPath((n1:Person)-[*..6]-(n2:Person)) toInt(\$expr) Find a single shortest path. Converts the given input into an integer if possible; allShortestPaths((n1:Person)-[*..6]->(n2:Person)) otherwise it returns null. Find all shortest paths. toFloat(\$expr) size((n)-->()-->()) Converts the given input into a floating point number if Count the paths matching the pattern. possible; otherwise it returns null. keys(\$expr) <u>Maps</u> Returns a list of string representations for the property {name: 'Alice', age: 38, names of a node, relationship, or map. address: {city: 'London', residential: true}} Literal maps are declared in curly braces much like **Path Functions** property maps. Nested maps and list are supported. length(path) MERGE (p:Person {name: \$map.name}) The number of relationships in the path. ON CREATE SET p = \$mapMaps can be passed in as parameters and used as map or nodes(path) The nodes in the path as a list. by accessing keys. relationships(path) MATCH (matchedNode:Person) The relationships in the path as a list. RETURN matchedNode Nodes and relationships are returned as maps of their extract(x IN nodes(path) | x.prop) data. Extract properties from the nodes in a path. map.name, map.age, map.children[0] Map entries can be accessed by their keys. Invalid keys **Mathematical Functions** result in an error. abs(\$expr) The absolute value. **Predicates** rand() n.property <> \$value Returns a random number in the range from 0 (inclusive) Use comparison operators. to 1 (exclusive), [0,1). Returns a new value for each call. Also useful for selecting subset or random ordering. exists(n.property) Use functions. round(\$expr) Round to the nearest integer, ceil and floor find the next n.number >= 1 AND n.number <= 10</pre> Use boolean operators to combine predicates. integer up or down. 1 <= n.number <= 10 sqrt(\$expr) Use chained operators to combine predicates. The square root. n:Person sign(\$expr) Check for node labels. o if zero, -1 if negative, 1 if positive. variable IS NULL sin(\$expr) Check if something is null. Trigonometric functions, also cos, tan, cot, asin, acos, atan, atan2, haversin. All arguments for the trigonometric NOT exists(n.property) OR n.property = \$value functions should be in radians, if not otherwise specified. Either property does not exist or predicate is true. degrees(\$expr), radians(\$expr), pi() n.property = \$value Converts radians into degrees, use radians for the reverse. Non-existing property returns null, which is not equal to pi for π. anything. log10(\$expr), log(\$expr), exp(\$expr), e() n["property"] = \$value Logarithm base 10, natural logarithm, e to the power of Properties may also be accessed using a dynamically the parameter. Value of e. computed property name. n.property STARTS WITH 'Tob' OR **String Functions** n.property ENDS WITH 'n' OR n.property CONTAINS 'goodie' toString(\$expression) String matching. String representation of the expression. n.property =~ 'Tob.*' replace(\$original, \$search, \$replacement) String regular expression matching. Replace all occurrences of search with replacement. All arguments must be expressions. (n)-[:KNOWS]->(m) Make sure the pattern has at least one match. substring(\$original, \$begin, \$subLength) Get part of a string. The subLength argument is optional. NOT (n)-[:KNOWS]->(m)Exclude matches to (n)-[:KNOWS]->(m) from the result. left(\$original, \$subLength), right(\$original, \$subLength) n.property IN [\$value1, \$value2] The first part of a string. The last part of the string. Check if an element exists in a list. trim(\$original), ltrim(\$original), rtrim(\$original) **CASE** Trim all whitespace, or on left or right side. CASE n.eyes upper(\$original), lower(\$original) WHEN 'blue' THEN 1 UPPERCASE and lowercase. WHEN 'brown' THEN 2 ELSE 3 split(\$original, \$delimiter) **END** Split a string into a list of strings. Return then value from the matching when value. The ELSE value is optional, and substituted for null if missing. reverse(\$original) Reverse a string. CASE WHEN n.eyes = 'blue' THEN 1 length(\$string) WHEN n.age < 40 THEN 2 Calculate the number of characters in the string. ELSE 3

```
Labels
```

CREATE (n:Person {name: \$value})

Create a node with label and property.

MERGE (n:Person {name: \$value})

Matches or creates unique node(s) with label and property.

SET n:Spouse:Parent:Employee Add label(s) to a node.

Matches nodes labeled Person.

MATCH (n:Person)

MATCH (n:Person)

WHERE n.name = \$value

Matches nodes labeled Person with the given name.

WHERE (n:Person)

Checks existence of label on node.

labels(n)

Relationship Functions

List Predicates

Returns true if the predicate is true for all elements of the

Returns true if the predicate is true for at least one

String representation of the relationship type.

type(a_relationship)

startNode(a_relationship)

endNode(a_relationship)

id(a_relationship)

list.

Start node of the relationship.

End node of the relationship.

The internal id of the relationship.

all(x IN coll WHERE exists(x.property))

any(x IN coll WHERE exists(x.property))

Patterns

(n:Person)

(n) - - > (m)

(n)--(m)

END

Return THEN value from the first WHEN predicate evaluating

to true. Predicates are evaluated in order.

(n:Person) --> (m)

Node with Person label.

(n:Person {name: \$value})

()-[r {name: \$value}]-()

Relationship from n to m.

Node with both Person and Swedish labels.

Matches relationships with the declared properties.

Relationship in any direction between n and m.

Node n labeled Person with relationship to m.

Node with the declared properties.

(n:Person:Swedish)

Labels of the node.

REMOVE n:Person

Remove label from node.

Lists

['a', 'b', 'c'] AS list

Literal lists are declared in square brackets.

Lists can be passed in as parameters.

range(\$firstNum, \$lastNum, \$step) AS list Range creates a list of numbers (step is optional), other

functions returning list are: labels, nodes, relationships, rels, filter, extract.

MATCH (a)-[r:KNOWS*]->() RETURN r AS rels Relationship variables of a variable length path contain a

list of relationships.

RETURN matchedNode.list[0] AS value,

size(matchedNode.list) AS len Properties can be lists of strings, numbers or booleans.

list[\$idx] AS value,

list[\$startIdx..\$endIdx] AS slice List elements can be accessed with idx subscripts in

square brackets. Invalid indexes return null. Slices can be retrieved with intervals from start_idx to end_idx each of which can be omitted or negative. Out of range elements are ignored.

UNWIND \$names AS name MATCH (n {name: name}) RETURN avg(n.age)

With UNWIND, you can transform any list back into individual rows. The example matches all names from a list of names.

MATCH (a)

RETURN [(a)-->(b) WHERE b.name = 'Bob' | b.age]

Pattern comprehensions may be used to do a custom projection from a match directly into a list.

List Expressions

size(\$list)

Number of elements in the list.

head(\$list), last(\$list), tail(\$list)

head returns the first, last the last element of the list. tail returns all but the first element. All return null for an empty list.

[x IN list WHERE x.prop <> \$value | x.prop]

Combination of filter and extract in a concise notation.

extract(x IN list | x.prop)

A list of the value of the expression for each element in the original list.

filter(x IN list WHERE x.prop <> \$value) A filtered list of the elements where the predicate is true.

reduce(s = "", x IN list | s + x.prop)

Evaluate expression for each element in the list, accumulate the results.

<u>Aggregation</u>

count(*)

The number of matching rows.

count(variable)

The number of non-null values.

count(DISTINCT variable)

All aggregation functions also take the distinct modifier, which removes duplicates from the values.

collect(n.property)

List from the values, ignores null.

sum(n.property)

Sum numerical values. Similar functions are avg, min, max.

percentileDisc(n.property, \$percentile)

Discrete percentile. Continuous percentile is

percentileCont. The percentile argument is from 0.0 to 1.0.

stdev(n.property)

Standard deviation for a sample of a population. For an entire population use stdevp.

Performance

- Use parameters instead of literals when possible. This allows Cypher to re-use your queries instead of having to parse and build new execution plans.
- Always set an upper limit for your variable length patterns. It's easy to have a query go wild and touch all nodes in a graph by mistake.
- Return only the data you need. Avoid returning whole nodes and relationships — instead, pick the data you need and return only that.
- Use PROFILE / EXPLAIN to analyze the performance of your queries. See **Query Tuning** for more information.
